

# Collaboration

Hamish Gibbs

# Collaboration

- Most programming isn't solo.
- In companies / research, you are often working on a small part of a larger project.
- To collaborate - you need to share code!

# Version control

- To collaborate, we need:
  - A place to store a shared version of our code.
  - A way to track changes to different parts of the code.
- Solution:
  - A “repository” to share our code
  - A **version control** system to track changes to the code

# Local vs. Remote code

- A repository stores the code for a specific project.
- There are two different types of repository:
  - **Local:**
    - *Think: a file folder on your computer.*
  - **Remote:**
    - *Think: a Google Drive folder.*

# Local vs. Remote code

- With version control, I want my **local** changes to be reflected in the **remote** repository.

# git and GitHub

- **git** is an open source version control system.
  - Purpose: recording and reconciling changes to code.
- **GitHub** is a place to store **remote** repositories.
  - Here is the repository for [this course!](#)

# Google docs

- `git` is kind of like Google Docs.
  - I make a change to a document.
  - You make changes to the same document.
  - Our changes are combined together.
- Except: `git` is *very manual*.

# Version control

- With `git` you need to be explicit about:
  - Saving **local** changes.
  - ‘Pushing’ **local** changes to the **remote** repository.
  - ‘Pulling’ changes from the **remote** repository.
  - Merging changes together.
- *Good question: Why does this have to be explicit?*

# Aims: this afternoon

- Create a **local** `git` repository with some of the code you have written.
- Create a **remote** repository on GitHub.
- Push your code from your **local** repository to your **remote** repository.

# Aims: tomorrow

- After the challenge, we will each:
  - Push our code to a shared repository.
  - Compare solutions.
- Shared repository URL:
  - [soda\\_python\\_foundations\\_challenge\\_2024](#)

# Tutorial #1

1. Setup a [GitHub](#) account.
2. [Create a GitHub repository](#).
3. Commit your **local** code ([Add](#), [Commit](#)).
4. Push your code to your **remote** repository ([Remote](#)).

# Extra

- If you breeze through the GitHub setup / repository creation:
  - Try editing files in the **remote**, then **pull** the changes to your **local** repository.
  - Try creating a **local branch**, then **push** the branch to the **remote** repository.
  - Try setting up a repository with someone else, making changes to the same file.

# Tip

- Github's Education Benefits give you access to a lot of **free stuff!**
  - GitHub Copilot
  - GitHub Copilot Chat
  - Free web hosting

# What about GitHub alternatives?

- [git](#) is open source and is the *de facto* version control software
- GitHub is a for-profit company owned by Microsoft.
- There are alternatives to GitHub:
  - [GitLab](#)
  - [CircleCI](#)
  - Many more...

# What about git clients?

- There are lots of (allegedly) “easier” ways to interact with `git` repositories through a graphical user interface (GUI).
  - Example: [GitHub Desktop](#).
- I recommend the command line because:
  - Most basic git interactions are simple commands.
  - You aren’t linked to a particular `git` hosting service.
